## Introduction to Database Systems

**Database Programming** 

Dr. Ramon Lawrence University of British Columbia Okanagan ramon.lawrence@ubc.ca

#### Database Programming Overview

Most user interaction with a database is through programs instead of directly using SQL commands to the database.

A programmer developing a database application executes SQL directly or indirectly in code using one of these methods:

- ◆standard application programming interfaces (APIs) such as
- ◆custom APIs specific to the database vendor
- ♦object-relational mapping technologies

All methods must process queries in code, send them to the database, retrieve database results, and map the result data into program variables so that they can be used by the program.

#### JDBC Overview

JDBC is the most popular method for accessing databases using Java programs.

JDBC is an application programming interface (API) that contains methods to connect to a database, execute queries, and retrieve results.

For each DBMS, the vendor writes a JDBC driver that implements the API. Application programs can access different DBMSs simply by changing the driver used in their program.

Page 3

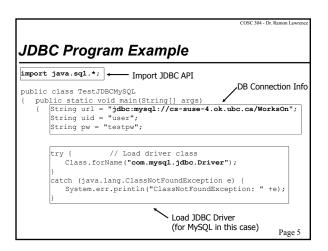

#### JDBC Interfaces

The JDBC API consists of a set of interfaces.

- ♦A Java interface is an abstract class consisting of a set of methods with no implementation.
- ◆To create a JDBC driver, the DBMS vendor must implement the interfaces by defining their own classes and writing the code for the methods in the interface.

The main user classes in the JDBC API are:

- ◆Driver The main class of the entire driver.
- ullet Connection For connecting to the DB using the driver.
- ◆Statement For executing a query using a connection.
- ◆ResultSet For storing and manipulating results returned by
- ◆DatabaseMetaData For retrieving metadata (schema) information from a database.

```
JDBC Program Example (2)
                                                    Make DB connection
       Connection con = null:
           con = DriverManager.getConnection(url, uid, pw);
Statement stmt = con.createStatement();
           ResultSet rst = stmt.executeQuery("SELECT ename, salary
Create
           System.out.println("Employee Name, Salary") Execute
statement
           while (rst.next())
              System.out.println(rst.getString("ename")
+","+rst.getDouble("salary"));
                                                              statement
                                                               Iterate
                                                               through
       catch (SQLException ex) { System.err.println(ex);}
       finally
          if (con != null)
               try
                  con.close();
               catch (SQLException ex) { System.err.println(ex); }
                                                                 Page 6
```

COSC 304 - Dr. Ramon Lauren

#### JDBC Driver Interface

The Driver interface is the main interface that must be implemented by a DBMS vendor when writing a JDBC driver.

◆The class itself does not do very much except allow a connection to be made to a database through the driver.

```
// Load and register driver with DriverManager
Class.forName("com.mysql.jdbc.Driver");
```

- ◆Note that you do not call the Driver class directly to get a connection. Rather, you load and register the driver with the DriverManager (using Class.forName()).
- ◆Then, when you call DriverManager.getConnection(), the DriverManager will attempt to locate a suitable driver from those loaded at initialization and those loaded explicitly.
- ◆The try ... catch block is required to make sure that the JVM finds the driver class in your CLASSPATH.

Page 7

COSC 304 - Dr. Ramon Lawren

#### JDBC Driver Interface (2)

The DriverManager determines which JDBC driver to use based on the URL used as a parameter:

The interface method <code>Driver.connect()</code> is called by the <code>DriverManager</code> on the driver object that will allow access based on the subprotocol specified in the URL.

- ♦ Inside this method the JDBC driver writer performs the actions to connect to the DBMS and returns a Connection object.
- ◆A try ... catch is also needed here if the driver is unable to successfully connect to the DB at the specified URL.

Page 8

COSC 304 - Dr. Ramon Lawrence

#### JDBC Driver Vendor Compliance

It is the responsibility of the DBMS vendor to create a JDBC driver to access their DBMS. Each vendor is free to provide any level of JDBC support that they desire.

- ◆Some methods in the JDBC API are not available on all drivers.
- ◆The basic support required is Entry Level SQL92.

Historical JDBC versions with key features:

- ◆JDBC 1.0 (1997) Driver, Connection, Statement, ResultSet, DatabaseMetadata, ResultSetMetaData
- ◆JDBC 2.0 (1999) BLOBs, updatable ResultSet, pooled connections
- ◆JDBC 3.0 (2001) improved transactions (savepoints), SQL99, retrieve auto-generated keys, update BLOBs
- ♦ JDBC 4.0 (2006) XML support, better BLOB support, auto driver loading, do not need Class.forName()  $p_{age}$  (

COSC 304 - Dr. Ramon Lawren

#### JDBC Connection Interface

The Connection interface contains abstract methods for managing a connection or session.

- ◆A connection is opened after the call to getConnection() and should be explicitly closed when you are done.
- ◆The Connection interface is used to create statements for execution on the database.

```
Connection con = DriverManager.getConnection(url, uid, pw);
Statement stmt = con.createStatement();
...
con.close();
```

Page 10

COSC 304 - Dr. Ramon Lawrence

#### Connection Interface and MetaData

A Connection to a database can also be used to retrieve the database metadata (or schema).

◆This is useful when you are writing generic tools where you do not know the schema of the database that you are querying in advance.

The method  $\tt getMetaData()$  can be used to retrieve a  $\tt DatabaseMetaData$  object.

Page 11

COSC 304 - Dr. Ramon Lawrence

#### DatabaseMetaData Example

Page 12

COSC 304 - Dr. Ramon Lawrence

#### DatabaseMetaData Example (2)

```
rs5 = dmd.getColumns(null,null,tblName,"%");
    System.out.println(" Attributes: ");
    while (rs5.next()) {
        System.out.println(rs5.getString(4));
    }
} // end outer while
} // end try
```

Page 13

COSC 304 - Dr. Ramon Lawren

#### JDBC Statement Interface

The Statement interface contains abstract methods for executing a single static SQL statement and returning the results it produces.

- ◆The Statement object is created by calling Connection.createStatement().
- ◆The statement is then executed by calling executeQuery() and passing the SQL string to execute.

Page 14

COSC 304 - Dr. Ramon Lawrence

#### JDBC Statement Interface (2)

There are two important variations of executing statements that are important and are used often.

◆1) The Statement executed is an INSERT, UPDATE, or DELETE and no results are expected to be returned:

```
rowcount = stmt.executeUpdate("UPDATE Emp Set salary=0");
```

◆2) The Statement executed is an INSERT which is creating a new record in a table whose primary key field is an autonumber field:

Page 15

COSC 304 - Dr. Ramon Lawrence

### PreparedStatement and CallableStatement

There are two special types of Statement objects:

- ◆PreparedStatement extends Statement and is used to execute precompiled SQL statements.
  - ⇒ Useful when executing the same statement multiple times with different parameters as the DBMS can optimize its parsing and execution.
  - $\mathop{\Rightarrow}\nolimits \mathsf{Also}$  useful to prevent SQL injection attacks.

```
String SQL = "UPDATE Emp SET salary = ? WHERE ID = ?";
PreparedStatement pstmt = con.prepareStatement(SQL);
pstmt.setBigDecimal(1, 55657.34); // Set parameters
pstmt.setString(2, "El");
int rowcount = pstmt.executeUpdate();
```

- ♦ CallableStatement extends PreparedStatement and is used to execute stored procedures.

COSC 304 - Dr. Ramon Lawrence

#### JDBC ResultSet

The ResultSet interface provides methods for manipulating the result returned by the SQL statement.

- ◆Remember that the result is a relation (table) which contains rows and columns.
- ◆The methods provide ways of navigating through the rows and then selecting columns of the current row.
- ◆A ResultSet object maintains a cursor pointing to its current row of data. Initially the cursor is positioned before the first row.
- ◆The next() method moves the cursor to the next row, and because it returns false when there are no more rows in the ResultSet object, it can be used in a while loop to iterate through the result set.

Page 17

COSC 304 - Dr. Ramon Lawrence

#### JDBC ResultSet (2)

By default a ResultSet is not *updatable* and the cursor can move *forward-only* (can only use next() method).

- ◆Remember, the first call to next() places the row cursor on the first row as the cursor starts off before the first row.
- $\bullet \mbox{Use}$  the  $\mbox{\tt getType}$  ( ) methods to retrieve a particular type.

```
⇒getArray(), getBlob(), getBoolean(), getClob(),
getDate(), getDouble(), getFloat(), getInt(),
getLong(), getObject(), getString(), getTime()
```

- ⇒ All methods take as a parameter the column index in the ResultSet (indexed from 1) or the column name and return the requested type.
- ⇒ Java will attempt to perform casting if the type you request is not the type returned by the database.
  Page 18

COSC 304 - Dr. Ramon Lauren

#### Scrollable ResultSets

It is also possible to request ResultSets that allow you to navigate backwards as well as forwards.

Scrollable ResultSets allow you to navigate in any direction through it, and these methods can now be used:

- ⇔absolute(int row) set cursor to point to the given row (starting at 1) ⇔afterLast(), beforeFirst(), first(), last(), next(), previous()
- ⇒ Scrollable ResultSets were introduced in JDBC 2.0 API and are less efficient than forward-only ResultSets.

COSC 304 - Dr. Ramon Lawren

#### Updatable ResultSets

Updatable ResultSets allow you to update fields in the query result and update entire rows.

Updating an existing row:

COSC 304 - Dr. Ramon Lawrence

#### Updatable ResultSets (2)

Adding a new row to a ResultSet:

Page 21

COSC 304 - Dr. Ramon Lawren

#### Custom APIs

Many databases have custom APIs for various languages.

◆For example, MySQL has APIs for C/C++ and PHP in addition to ODBC and JDBC drivers.

When to use a custom API?

- ◆Custom APIs may be useful when the ODBC/JDBC standard does not provide sufficient functionality.
- ◆Also useful if *know* that application will only access one database. (Be careful with this .. think of the future).

Custom APIs may have improved performance and increased functionality. The disadvantage is that your code is written for a specific DBMS which makes changes difficult.

◆If you use a custom API, always isolate the database access code to a few general classes and methods! Page 22

COSC 304 - Dr. Ramon Lawrence

### Aside: Direct Connection using Driver

It is possible to directly create a driver class object and call its connect method instead of using <code>DriverManager</code>.

♦NOT recommended as puts vendor specific code in your code!

```
// Create new structure for passing info to database
Properties prop = new Properties();
prop.put("user", "rlawrenc");
prop.put("password", "pw");

Connection con = null;
try {
    Driver d = new com.mysql.jdbc.Driver();
    con = d.connect(url, prop);
```

This also demonstrates the use of the Properties class that allows you to pass key/value pairs to the database that are not in the URL. Can also use with DriverManager:

```
con = DriverManager.getConnection(url, prop);
```

COSC 304 - Dr. Ramon Lawre

### Aside:

#### Making a Connection using DataSource

 ${\tt DataSource} \ in \ package \ {\tt java.sqlx} \ is \ the \ preferred \ way for connecting to a database as it hides the URL and vendor specific code (if used in conjunction with JNDI).$ 

```
import javax.sql.DataSource;
import com.mysql.jdbc.jdbc2.optional.*;

MysqlDataSource ds = new MysqlDataSource();
ds.setUser("rlawrenc");
ds.setDassword("pw");
ds.setServerName("cs-suse-4.ok.ubc.ca");
ds.setDatabaseName("WorksOn");
con = ds.getConnection();
```

Note without Java Naming and Directory Interface (JNDI) that vendor specific code is still in the application.

Page 24

# Object-Relational Mapping Java Persistence Architecture (JPA)

A huge challenge with database programming is converting the database results to and from Java objects. This is called object-relational mapping, and it is tedious and error-prone.

◆Impedance mismatch - Database returns values in tables and rows and Java code manipulates objects, classes, and methods.

Various vendors (e.g. Hibernate) have produced objectrelational mapping technologies that help the programmer convert database results into Java objects.

Recently, the Java Persistence Architecture (JPA) has been developed as a standard interface. Vendors can then implement the interface in their products.

Page 25

COSC 304 - Dr. Ramon Lawrence

#### JDBC Question

Create a JDBC program that:

- ◆Connects to WorksOn database on cs-suse-4.ok.ubc.ca.
- ◆Prints on the console each department and its list of projects.

#### Challenge:

◆Improve your code so that it prints the department number, name, and how many projects in that department THEN the list of projects.

Page 26

COSC 304 - Dr. Ramon Lawrence

#### Conclusion

JDBC is a standard APIs for connecting to databases using Java. Querying using JDBC has these steps:

- ♦Load a Driver for the database
- ◆Make a Connection
- ◆Create a Statement
- ◆Execute a query to produce a ResultSet
- ♦Navigate the ResultSet to display results or update the DB

There are other ways for accessing a database:

- ◆Custom APIs specific to each database vendor
- ♦object-relational mapping and JPA

 $\it Java\ Persistence\ Architecture\ (\it JPA)$  is a standard API for object-relational mapping.

Page 27

COSC 304 - Dr. Ramon Lawrer

#### **Objectives**

- ◆Explain the general steps in querying a database using Java.
- ◆List the main JDBC classes (Driver, Connection, Statement, ResultSet) and explain the role of each in a typical program.
- ♦Discuss the different types of ResultSets including scrollable and updatable ResultSets.
- ◆Write a simple JDBC program (given methods of the JDBC API).
- ◆Discuss and explain the advantages and disadvantages of using a standard API versus a vendor-based APIs.
- ◆Explain object-relational mapping and the impedance mismatch.

Page 28
